# Central theme/claim

---

- *“To researchers’ surprise, deep learning vision algorithms **often fail** at classifying images because they mostly take cues from textures, not shapes.”*

\*Henceforth, an asterix indicates my own thoughts additional to the paper

Department of Medicine

# Central theme/claim

---

- *“To researchers’ surprise, deep learning vision algorithms **often fail** at classifying images because they mostly take cues from textures, not shapes.”*
  - DL **often succeeds** (internal validation)\*
  - But **fails** to generalize (ext. validation)\*
    - other machines, environments, cases; adversarial inputs

# Experiment: painting cats with elephant skin

- *The classifier identified an elephant (by texture)*
- *Humans identified a cat (by shape)*
  - This is an adversarial example which may not be realistic for all domains, e.g., surgery\*
    - Mimics, obstructions and noise are different. Obstructions confuse shape.\*
    - i.e., which feature trumps? who is right?

# This raises a bigger question\*

---

- Do we want computers to:
  - Think like us?\*
  - Or differently (to compliment our thinking)?\*
    - It depends on the application/objective\*
    - It can be useful or ideal to have votes (or probabilities of class membership) from:\*
      - a shape classifier\* **and**
      - a texture classifier\*

# Experiment: making DL use shapes

---

- Paint irrelevant textures (on objects, background)
- Performance improved
- But the classifier could still be fooled with trivial changes
